*The Journal of Rheumatology* is a monthly international serial edited by Earl D. Silverman featuring research articles on clinical subjects from scientists working in rheumatology and related fields.
Severe Sensory Neuronopathy in Primary Sjögren Syndrome Resulting in Charcot Arthropathy

To the Editor:

Sjögren syndrome (SS), an autoimmune disorder affecting the exocrine glands, is known to have many extraglandular manifestations including peripheral neuropathy. In the setting of an underlying neuropathy, progressive joint destruction is known as Charcot arthropathy.

We present a case of a 68-year-old woman with known SS presenting with functional loss of the right arm. She had presented initially 15 years earlier with keratoconjunctivitis sicca, arthralgias, and complaints of numbness and tingling of the right arm and both hands, and a positive antinuclear antibody (ANA). A diagnosis of SS was made; however, the patient was subsequently lost to followup. She was re-referred with a 6-month history of right shoulder pain. Rheumatology assessment revealed a 15-year history of right arm numbness, keratoconjunctivitis sicca, xerostomia, arthralgias, and fatigue. On history she reported an insensate right arm for “many years,” as well as a recent decrease in right leg sensation. There were no additional connective tissue disease symptoms other than an intermittent facial rash. Her medical history was otherwise unremarkable and she was not taking any medications. Examination revealed edentulousness, bilateral clouded corneas, and a mild symmetric polyarthritis. The entire right arm was insensate with profound proprioceptive loss. The entire right leg had decreased sensation to light touch, pinprick, and vibration. Deep tendon reflexes were absent with no plantar reflexes. Range of motion, motor function, and gait were normal and she ambulated independently. Cranial nerve examination was unremarkable. Serology was significant for a high-titer ANA. Extractable nuclear antigens including Ro and La antibodies, dsDNA antibody, and rheumatoid factor were negative. Both the erythrocyte sedimentation rate and C-reactive protein were elevated at 65 mm/h and 24 mg/l, respectively. Radiographic imaging of the right shoulder showed destruction of the right humeral head and glenoid, which had progressed rapidly compared to the radiographic imaging 3 months prior. Radiographic imaging of the cervical and thoracic spine showed no evidence of syringomyelia and no other abnormalities; Glenohumeral joint aspiration yielded no bacterial growth. Nerve conduction studies (NCS) revealed a widespread sensory neuropathy including all 4 limbs with intact motor function and no evidence of demyelination, and was considered most likely to be neuronopathy. Electromyography was normal.

The patient was diagnosed with Charcot arthropathy of the shoulder resulting from sensory neuropathy because of primary SS. Treatment was initiated with hydroxychloroquine, low-dose prednisone, and 2 g/kg of monthly intravenous immunoglobulin (IVIG). She had subjective improvement in her right leg paraesthesias as well as in arthralgias and fatigue, but no improvement in the right arm. Repeat NCS 1 year later revealed ongoing sensory neuropathy in both hands. After a total of 20 months of IVIG therapy, a third NCS showed ongoing sensory neuropathy with worsening of the left radial sensory response. The patient then presented with painless left foot swelling and was found to have an atraumatic, posterior calcaneal fracture suspicious for a Charcot joint about 2 years after treatment was initiated (Figure 2).

Sensory neuropathy, autonomic dysfunction, and loss of protective pain and proprioceptive sensation are thought to predispose a joint to Charcot arthropathy. Charcot arthropathy is associated with diabetes mellitus, syringomyelia, spinal cord lesions, cerebral palsy, polio, leprosy, tabes dorsalis, and chronic alcoholism. To our knowledge, no literature to date, however, has described the development of Charcot arthropathy in the setting of primary SS–associated sensory neuronopathy. Sensory neuronopathy is also called sensory ganglonopathy and ataxic sensory neuropathy. It has a prevalence of 5% to 39% of peripheral neuropathies in SS and its predominant feature is proprioceptive loss. It commonly presents with initial distal symptoms and a subacute or chronic onset.

A cohort study of 36 patients with sensory neuronopathy found that 53% and 11% have anti-Ro and anti-La antibodies, respectively. Electrodiagnostics reveal an absence of sensory-evoked responses with intact motor responses, consistent with our patient’s findings. Nerve biopsies have shown destruction of the sensory ganglia in the dorsal root ganglia with mononuclear cell infiltration and loss of myelinated fiber density; these findings were confirmed in an autopsy study. Data regarding the treatment of primary SS-associated sensory neuronopathy stems from observational studies and case series. Limited responses to corticosteroids, cyclophosphamide, plasmapheresis, azathioprine, infliximab, rituximab, and D-penicillamine have been described. There have also been variable responses to IVIG therapy. Despite treatment, most patients had an indolent course in the longterm followup of their neurological symptoms.

This case illustrates a severe complication of longstanding and untreated sensory neuronopathy. The severity of the presentation and response to treatment highlight the potential for orthopedic complications and the need for routine surveillance of patients with primary SS.
sensory neuronopathy. Though there was subjective improvement with IVIG therapy in this patient, repeat NCS showed progression of the neuronopathy and the patient developed a second Charcot joint. Monitoring of patients for the development of neurological manifestations is warranted because some patients may benefit from therapy. Further studies are necessary to determine the optimal treatment and treatment duration for patients with SS-associated sensory neuronopathies.
