

PTPN22 R620W Polymorphism and ANCA Disease Risk in White Populations: A Metaanalysis

Yali Cao, Kuo Liu, Zhigang Tian, Susan L. Hogan, Jiajin Yang, Caroline J. Poulton, Ronald J. Falk, and Wenge Li

ABSTRACT. Objective. No clear consensus has been reached on the *PTPN22* R620W polymorphism and anti-neutrophil cytoplasmic antibody (ANCA) disease, especially when stratified by ANCA specificity and disease phenotypes.

Methods. A metaanalysis was conducted on the *PTPN22* R620W polymorphism across 4 studies in 1399 white patients with ANCA disease and 9934 normal control subjects.

Results. Overall, metaanalysis showed a statistically significant association between the A allele and ANCA disease in all subjects (OR 1.44, 95% CI 1.26–1.64, $p < 0.00001$), and stratification by disease category indicated the A allele was associated with granulomatosis with polyangiitis (Wegener's; GPA; OR 1.72, 95% CI 1.35–2.20, $p < 0.0001$) and microscopic polyangiitis (MPA; OR 1.53, 95% CI 1.08–2.15, $p = 0.02$) as compared to controls. However, when stratified by ANCA specificity, the association of the A allele was statistically evident among those with proteinase 3 (PR3) ANCA disease (OR 1.74, 95% CI 1.25–2.430, $p = 0.001$), with the same trend but not statistically associated with myeloperoxidase ANCA disease (OR 1.94, 95% CI 0.64–5.85, $p = 0.24$). The marked associations were also demonstrated between this allele with lung (OR 1.69, 95% CI 1.21–2.36, $p = 0.002$), ENT (OR 2.03, 95% CI 1.45–2.84, $p < 0.0001$), skin (OR 2.55, 95% CI 1.69–3.84, $p < 0.0001$), and peripheral neuropathy involvement (OR 2.12, 95% CI 1.39–3.22, $p = 0.0005$).

Conclusion. The *PTPN22* 620W allele confers susceptibility to the occurrence and development of ANCA disease in whites, with specific evidence among subsets with GPA, MPA, and PR3 ANCA. (J Rheumatol First Release Dec 1 2014; doi:10.3899/jrheum.131430)

vessels. ANCA is categorized into several disease groups, including granulomatosis with polyangiitis (Wegener's; GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA), as proposed by the Chapel Hill Consensus Conference¹.

The cause of ANCA disease is not clear. Although both environmental factors² and epigenetic changes³ have been implicated, the molecular genetics of ANCA contributes significantly to the pathogenesis of the disease⁴. In 2004, a single nucleotide polymorphism (SNP) in the protein tyrosine phosphatase nonreceptor 22 (*PTPN22*) gene (R620W, rs2476601, C1858T) was identified; it caused a protein modification, which disrupted the regulatory domain of the phosphatase, conferring a gain-of-function phenotype. It has been demonstrated that this genetic variant is associated with numerous other autoimmune diseases including type 1 diabetes^{5,6,7,8,9}, rheumatoid arthritis^{10,11,12,13,14,15}, and systemic lupus erythematosus^{16,17,18}. Later this genetic variant was demonstrated to be linked with ANCA disease in 4 studies^{19,20,21,22}. However, as a rare autoimmune disease, the number of patients was relatively small within each individual study. Further, a genome-wide association study

(GWAS) suggested that proteinase 3 (PR3) and myeloperoxidase (MPO) had distinct genetic origins⁴. The published genetic association results for the *PTPN22* R620W polymorphism are controversial and inconclusive when the disease is stratified by clinical phenotype and ANCA specificity, a practice that might be due to small sample sizes, low statistical power, and/or clinical heterogeneity. Therefore, to overcome the limitations of individual studies and resolve inconsistencies, we turned to metaanalysis in the subgroup of ANCA disease. We investigated whether the *PTPN22* R620W polymorphism contributes to the susceptibility of ANCA diseases and their subtypes using a metaanalysis approach.

MATERIALS AND METHODS

Identification and eligibility of relevant studies. To identify all studies that examined the association of *PTPN22* R620W (rs 2476601) polymorphism with ANCA disease, we performed a systematic, computerized literature search of the PubMed database, Embase, and the Cochrane library (up to August 2013) using the following various combinations of keywords and subject terms: “tyrosine phosphatase non-receptor 22” OR “*PTPN22*”, “polymorphism” OR “polymorphisms” and “anti-neutrophil cytoplasmic antibody” OR “ANCA” OR “AAV” (ANCA-associated vasculitis).

We also retrieved additional studies through the MEDLINE option “related articles.” Search results were limited to research articles in English and studies on human subjects without country restrictions. The full text of the retrieved articles was scrutinized to decide whether information on the topic of interest was included. Studies included in the metaanalysis had to meet all the following criteria: (1) use of cases compared to unrelated controls (either retrospective or cross-sectional), (2) available genotype frequency, (3) a genotype distribution of the control population consistent with Hardy–Weinberg equilibrium (HWE). All the patients met the criteria of the Chapel Hill consensus conference definition for GPA, MPA, and EGPA¹.

Data extraction. To extract the information needed, all articles were separately collected and reviewed by 2 independent investigators (YC, KL) who checked for any discordance and reached a consensus. If they could not come to an agreement, a third investigator adjudicated the disagreements. The following information was collected from the studies on the genotype of *PTPN22* R620W: first author, year of publication, full citation information, country, sample sizes of cases and controls, genotype numbers, allele frequency in both cases and controls, and p values of HWE in controls. Allele frequency in cases by disease category and ANCA specificity were also collected.

Statistical analysis. The strength of the association of Arg620Trp (R620W) with ANCA disease was measured by OR compared to controls, with corresponding 95% CI calculated according to the method of Woolf²³. We examined the association between the W allele of *PTPN22* R620W and ANCA disease risk (A vs G), the dominant genetic model (AA + GA vs GG), the recessive genetic model (AA vs GA + GG), and homozygote comparison (AA vs GG). In our study, 2 models of metaanalysis were used for dichotomous outcomes in the Review-Manager 5.2 software: the fixed-effects model and the random-effects model. The fixed-effects model used the Peto Mantel–Haenszel method, which assumes that studies are sampled from populations with the same effect size, and adjusts the study weights according to the in-study variance. The random-effects model used the Der Simonian and Laird’s method, which assumes that the studies are taken from populations with varying effect sizes, and calculates the study weights both from in-study and between-study variances, considering the extent of variation or heterogeneity. We performed a chi-squared Q statistic test to assess between-study heterogeneity²⁴. Heterogeneity was considered significant for $p < 0.10$ because of the low power of the statistic. The incon-

sistency index I^2 was also calculated to evaluate the variation that was caused by heterogeneity rather than by chance, and higher values of the index indicated the existence of heterogeneity²⁵. A p value > 0.10 for the Q-test indicates a lack of heterogeneity among studies, and the pooled OR estimate of each study was calculated with the fixed-effects model²⁶. Otherwise, the random-effects model was used²⁷. The significance of the pooled OR was determined by the Z test and a p value of < 0.05 was considered significant. The same methods were used comparing subgroups based on ANCA specificity, disease specificity, and organ involvement to controls.

In addition, an estimate of potential publication bias was carried out by the funnel plot, with an asymmetric plot indicating possible publication bias. HWE was tested by the chi-square test for goodness-of-fit based on a Web program (www.ihg.gsf.de/cgi-bin/hw/hwa1.pl). Analyses were performed using the software Review-Manager 5.2. All p values were 2-sided.

RESULTS

Description of studies identified in metaanalysis. Figure 1 shows the flow chart summarizing the process of study selection and reasons for exclusion. The GWAS mentioned in introduction was not included because the *PTPN22* R620W allele was not included in the GWAS study. Six relevant studies were identified that examined the association between polymorphisms of *PTPN22* R620W and ANCA vasculitis. Two studies were excluded because they were metaanalyses used to determine the association between *PTPN22* R620W and vasculitis, including Takayasu arteritis, Henoch–Schönlein purpura, Behçet disease, giant cell arteritis, and ANCA-associated²⁷ or other autoimmune diseases²⁸. Thus, 4 studies met the inclusion criteria^{19,20,21,22} and involved a total of 1399 patients and 9934 controls. There was 1 study each in Germany, the United Kingdom, Italy, and the United States. All cases and controls involved in these studies were white. The pooled overall frequencies of the A allele were 11.62% and 9.11% in ANCA cases and in controls, respectively. Detailed information on eligible studies, sample size, the distribution of R620W genotypes, A allele frequencies of cases and controls, and p values of HWE in controls are described in Tables 1a and 1b.

***PTPN22* R620W polymorphism conferred susceptibility to ANCA disease.** For each study, we investigated the association between the *PTPN22* R620W polymorphisms and ANCA disease risk, assuming different inheritance models of the 620W allele (Table 2). Overall, when all the eligible studies were pooled into the metaanalysis, significant associations between *PTPN22* R620W polymorphism and ANCA susceptibility were observed in all genetic models, including allele comparison (A vs G: $p < 0.00001$, OR 1.44, 95% CI 1.26–1.64, $P_{\text{heterogeneity}}$ 0.87; Figure 2a), dominant genetic model (AA + GA vs GG: $p < 0.00001$, OR 1.48, 95% CI 1.28–1.70, $P_{\text{heterogeneity}}$ 0.89; Figure 2b), recessive genetic model (AA vs GA + GG: $p = 0.03$, OR 1.80, 95% CI 1.07–3.02, $P_{\text{heterogeneity}}$ 0.92; Figure 2c), and homozygote comparison (AA vs GG: $p = 0.01$, OR 1.94, 95% CI 1.15–3.25, $P_{\text{heterogeneity}}$ 0.91; Figure 2d).

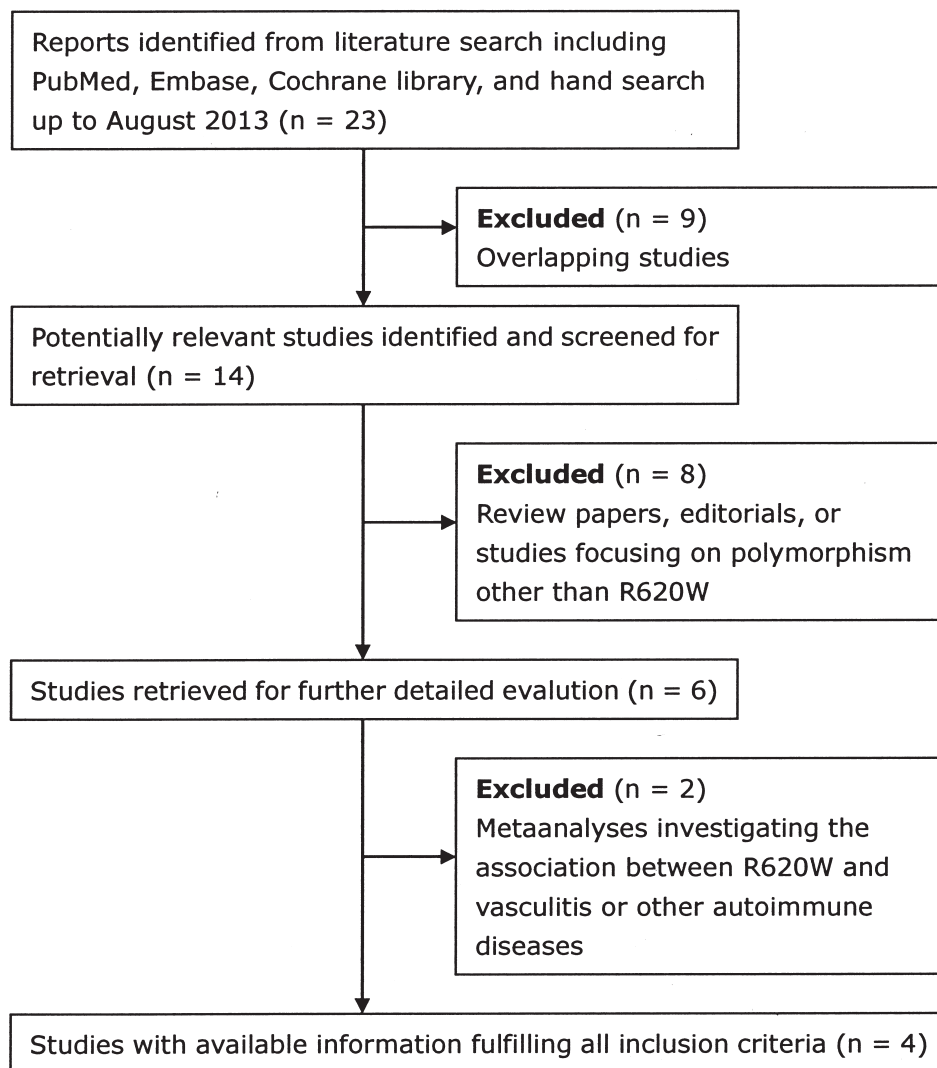

Figure 1. Flow chart of selection of studies and specific reasons for exclusion from the metaanalysis.

Significant association identified in the *PTPN22* R620W polymorphism with both GPA and MPA. When all the available data were pooled into the metaanalysis (Table 2), a significant association between *PTPN22* R620W polymorphism and GPA susceptibility was observed in allele comparison (A vs G $p < 0.0001$, OR 1.72, 95% CI 1.35–2.20, $P_{\text{heterogeneity}} = 0.87$; Figure 3a). A similar result was also observed in the MPA subgroup (A vs G: $p = 0.02$, OR 1.53, 95% CI 1.08–2.15, $P_{\text{heterogeneity}} = 0.86$; Figure 3b).

PTPN22 R620W polymorphism was significantly correlated with PR3-ANCA serotype, but inconclusive with the MPO-ANCA serotype. We pooled the available data into the metaanalysis and found that there was a significant association between *PTPN22* R620W polymorphism and PR3-ANCA in allele comparison (A vs G: $p = 0.001$, OR 1.74, 95% CI 1.25–2.43, $P_{\text{heterogeneity}} = 0.74$; Figure 3c). However, carriage of this variant allele was inconclusive with MPO-ANCA serotype in allele comparison, with a

large association but also a wide CI that crossed and equaled OR (1.0; A vs G: $p = 0.24$, OR 1.94, 95% CI 0.64–5.85, $P_{\text{heterogeneity}} = 0.04$; Table 2, Figure 3d).

PTPN22 R620W polymorphism association with organ involvement. Further analysis of this polymorphism focused on its association with organ involvement. Organ involvement in the patients with AAV was assessed by physical examination, routine laboratory tests, and a standardized set of imaging studies. Two available datasets from Italy and the United States were pooled for this analysis. The 620W allele was significantly associated with lung involvement (A vs G: $p = 0.002$, OR 1.69, 95% CI 1.21–2.36, $P_{\text{heterogeneity}} = 0.35$), ENT involvement (A vs G: $p < 0.0001$, OR 2.03, 95% CI 1.45–2.84, $P_{\text{heterogeneity}} = 0.90$), skin involvement (A vs G: $p < 0.00001$, OR 2.55, 95% CI 1.69–3.84, $P_{\text{heterogeneity}} = 0.20$) and peripheral neuropathy involvement (A vs G: $p = 0.0005$, OR 2.12, 95% CI 1.39–3.22, $P_{\text{heterogeneity}} = 0.68$). This allele was positively but

not statistically associated with kidney involvement (A vs G: $p = 0.20$, OR 1.44, 95% CI 0.82–2.53, $P_{\text{heterogeneity}} = 0.09$; Table 3).

Heterogeneity and publication bias. The shape of the funnel plot did not reveal any evidence of obvious asymmetry, and no evidence of publication bias was found in the meta-analysis (Appendix 1).

DISCUSSION

This is the largest systematic review to date, to our knowledge, investigating the association between *PTPN22* R620W polymorphism and ANCA disease. Compared with the metaanalysis of 3 studies by Lee, *et al*²⁷, our

metaanalysis included 4 studies with 1399 patients and 9934 controls. Our study also included stratified metaanalyses based on ANCA type and disease specificity. Consistent with the former metaanalysis, we observed a significant association between the *PTPN22* R620W polymorphism and susceptibility to ANCA disease. The GWAS by Lyons, *et al* did not find the association between *PTPN22* and ANCA disease⁴. However, they did not directly type rs2476601 in the GWAS study but instead typed rs6679677. Perhaps the 2 SNP could not tag each other perfectly. We had a large number of patients enrolled in our study and conducted further subgroup analysis, which showed the association of the disease-associated allele skewed toward

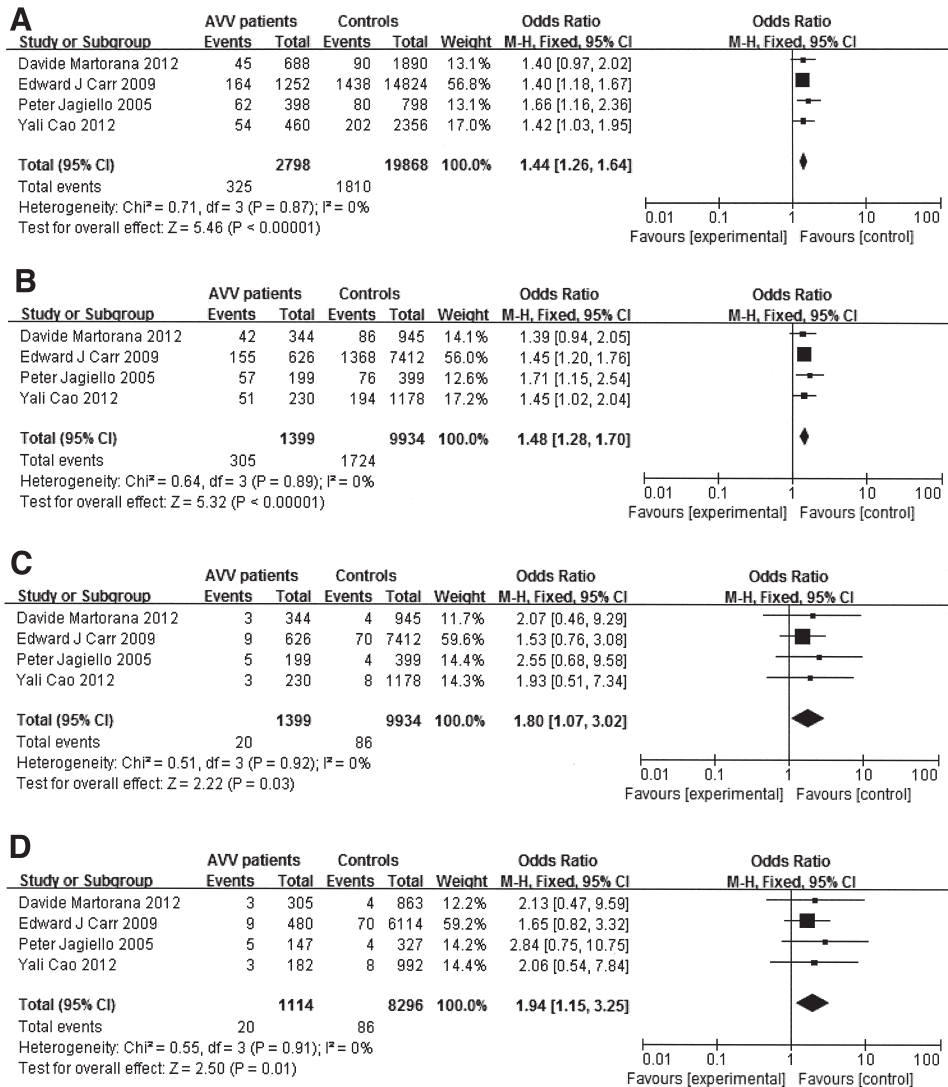

Figure 2. Association between *PTPN22* R620W polymorphism and antineutrophil cytoplasmic antibodies (ANCA) disease risk. Figure 2a shows the association between *PTPN22* R620W polymorphism and ANCA disease in allele comparison (A vs G). Figure 2b shows the association between R620W polymorphism and ANCA disease under the dominant genetic model (AA + GA vs GG). Figure 2c shows the association between R620W polymorphism and ANCA disease under recessive genetic model (AA vs GA + GG). Figure 2d shows the association between R620W polymorphism and ANCA disease in homozygote comparison (AA vs GG). AVV: ANCA-associated vasculitis; M-H: Mantel-Haenszel test.

PR3-ANCA disease, and suggested but did not detect an association for MPO-ANCA disease. Considering the small sample size and limited statistical power, future studies based on large-scale investigation are needed to further validate the association of *PTPN22* 620W polymorphism and MPO-ANCA disease in a white population.

Our metaanalysis reinforces the strength of the association between the R620W and susceptibility to both GPA and MPA. GPA and MPA are 2 distinct yet overlapping syndromes of AAV. It has been demonstrated that the strongest genetic associations were with the antigenic specificity of ANCA, rather than with the clinical syndrome⁴. The

results of our metaanalysis were consistent with this conclusion. However, our results should be interpreted with caution because only 2 studies provided data in the subgroup of ANCA specificity. In addition, the results of the 2 above studies^{21,22} were positive for PR3-ANCA disease and neither was statistically significant for MPO-ANCA disease. This might be explained by the geographical and genetic factors involved in the pathogenesis of ANCA disease. Prevalence of ANCA type varies across geographic regions, with PR3-ANCA being more common in northern European populations and MPO-ANCA more common in southern European countries^{29,30,31}. US cohorts suggested

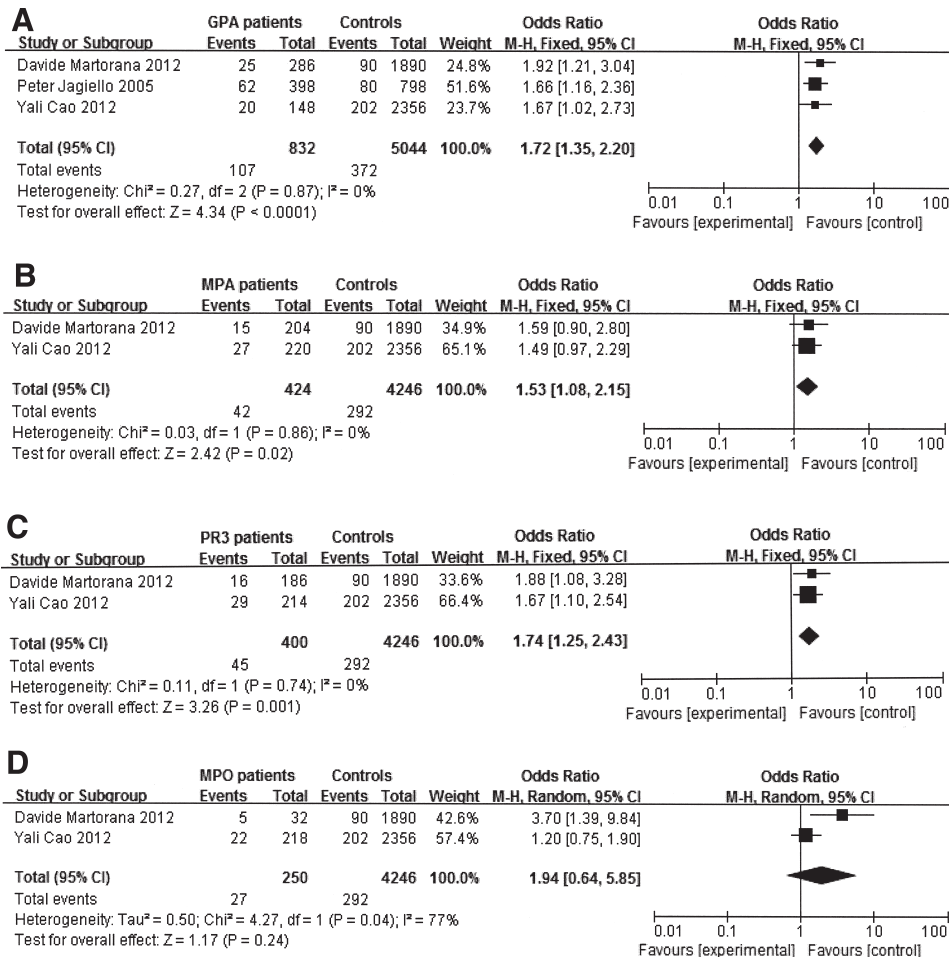

Figure 3. Association between *PTPN22* R620W polymorphism and antineutrophil cytoplasmic antibodies (ANCA) disease stratified by disease phenotype and ANCA serology. Figure 3a shows the association between *PTPN22* R620W polymorphism and granulomatosis with polyangiitis (GPA) in allele comparison (A vs G). Figure 3b shows the association between *PTPN22* R620W polymorphism and microscopic polyangiitis (MPA) in allele comparison (A vs G). Figure 3c shows the association between *PTPN22* R620W polymorphism and proteinase 3 (PR3)-ANCA disease in allele comparison (A vs G). Figure 3d shows the association between *PTPN22* R620W polymorphism and myeloperoxidase (MPO)-ANCA disease in allele comparison (A vs G). M-H: Mantel-Haenszel test.

F: fixed effects model; R: random effects model.

that PR3-ANCA was more prevalent in whites than in African Americans³². Additionally, MPO-ANCA is predominant in Asian countries^{33,34}. The geographic distribution of this variant allele is highest in countries where PR3-ANCA

is predominant. The allele is nearly absent in African American and Asian populations³⁵.

In the present metaanalysis, the genotypic-phenotypic associations were also investigated. In the US study²², the A

allele was particularly associated with lung, ENT, skin, and peripheral nervous system involvement. The Italian group²¹ instead found that this allele was enriched predominantly in GPA patients with ENT involvement, lung involvement, and skin lesions other than purpura. Our results seem to point to a particular association between the *PTPN22* SNP and a PR3-ANCA disease pattern. It has been noted that patients with the most compelling evidence for necrotizing granulomatous inflammation are most likely to have PR3-ANCA³⁶. Skin lesions and peripheral neuropathy may be granulomatous and are common phenotypes in PR3-ANCA disease³⁷. Interestingly, *PTPN22* is thought to be involved in granuloma formation³⁸.

The results of our metaanalysis should be interpreted within the context of its limitations. First, we focused only on papers published in the English language, so some local literature biases were inevitable. Second, only a small number of studies were conducted on the subgroup of ANCA disease, which may mean that our investigation was underpowered. Third, our ethnic-specific metaanalysis was performed using data from white patients, and thus our results are only applicable to this ethnic group. Further studies are required in different ethnic populations, because the prevalence of the *PTPN22* R620W polymorphism is ethnicity-dependent. Fourth, the results for publication bias should be interpreted with caution, given the relatively small number of available studies.

Our metaanalysis demonstrates that the *PTPN22* R620W polymorphism confers susceptibility to ANCA disease in whites. In contrast, carriage of this variant allele was inconclusive with the MPO-ANCA serotype, which needs to be studied in larger samples.
