 Outcome Measures in Acute Gout: A Systematic Literature Review

Nicola Dalbeth, Cathy S. Zhong, Rebecca Grainger, Dinesh Khanna, Puja P. Khanna, Jasvinder A. Singh, Fiona M. McQueen, and William J. Taylor

ABSTRACT. Objective. Five core domains have been endorsed by Outcome Measures in Rheumatology (OMERACT) for acute gout: pain, joint swelling, joint tenderness, patient global assessment, and activity limitation. We evaluated instruments for these domains according to the OMERACT filter: truth, feasibility, and discrimination.

Methods. A systematic search strategy for instruments used to measure the acute gout core domains was formulated. For each method, articles were assessed by 2 reviewers to summarize information according to the specific components of the OMERACT filter.

Results. Seventy-seven articles and abstracts met the inclusion criteria. Pain was most frequently reported (76 studies, 20 instruments). The pain instruments used most often were 100 mm visual analog scale (VAS) and 5-point Likert scale. Both methods have high feasibility, face and content validity, and within- and between-group discrimination. Four-point Likert scales assessing index joint swelling and tenderness have been used in numerous acute gout studies; these instruments are feasible, with high face and content validity, and show within- and between-group discrimination. Five-point Patient Global Assessment of Response to Treatment (PGART) scales are feasible and valid, and show within- and between-group discrimination. Measures of activity limitations were infrequently reported, and insufficient data were available to make definite assessments of the instruments for this domain.

Conclusion. Many different instruments have been used to assess the acute gout core domains. Pain VAS and 5-point Likert scales, 4-point Likert scales of index joint swelling and tenderness and 5-point PGART instruments meet the criteria for the OMERACT filter. (First Release Dec 15 2013; J Rheumatol 2014;41:558–68; doi:10.3899/jrheum.131244)

Key Indexing Terms:
GOUT PAIN MEASUREMENT OUTCOME

Acute gout is characterized by the sudden onset of intense pain and swelling of 1 or more joints, reaching a maximal level of severity within hours and usually resolving over 10–14 days. The aim of therapy for acute gout is rapid resolution of the attack. Typically, acute gout is treated with nonsteroidal antiinflammatory drugs (NSAID), corticosteroids, or colchicine. There has been renewed interest in the treatment of acute gout since the identification of the central role of the NLRP3 inflammasome and interleukin 1β (IL-1β) in initiation of the inflammatory response to monosodium urate crystals. This has led to recent clinical trials of IL-1β inhibitors for management of acute gout.

Since 2002, the Outcome Measures in Rheumatology (OMERACT) Gout Special Interest Group has worked toward defining outcome measures for studies in gout. Five core domains have been endorsed by OMERACT for studies of acute gout: pain, joint tenderness, joint swelling, patient global assessment, and activity limitation. Although these domains have been endorsed for acute gout trials, the instruments for each of

these domains have not been fully developed nor endorsed by the OMERACT process for this context. The aim of this systematic literature review was to evaluate instruments for the acute gout core domains according to the OMERACT filter: truth, feasibility, and discrimination. A systematic search strategy was formulated to provide a written summary of the evidence for instruments in the acute gout core domains endorsed by OMERACT. The research question was which instruments assessing the core domains in acute gout met the OMERACT filter. The following search keywords were used: “acute gout,” “gout flare,” “gouty arthritis,” “gout pain,” “gout randomized control trial,” “gout attack,” “gout tenderness,” “gout swelling,” “gout patient global,” “gout outcome,” and “gout activity.” Searches were performed in the following electronic databases: PubMed, Medline, Cochrane Central Register of Controlled Trials (The Cochrane Library), Excerpta Medica Database (EMBASE), European League Against Rheumatism (EULAR) meeting abstract archive, and American College of Rheumatology (ACR) Annual Scientific Meeting abstract archive.

Bibliographical references of individual publications were also checked. Data sources were English publications from these databases, and hand searches. No date restrictions were used (earliest database search date was 1946). The search was completed in December 2011. An example of the search strategy is shown in Figure 1A. Articles and abstracts were included if the participants had acute gout, and at least 1 core domain was assessed in the study. The search results were further cross-checked with the results of an independent systemic literature review of randomized controlled trials (RCT) for treatments of acute gout to ensure that all relevant RCT studies were identified. A total of 6942 articles were generated by the search, with 4680 excluded whose titles did not correlate to acute gout. Case reports, prevalence studies, studies of conditions other than acute gout, or those that did not address any aspect of the OMERACT filter were further excluded based on abstract or full text review. A total of 77 abstracts and full-text articles met inclusion criteria and were included in the analysis (Figure 1).

For each outcome domain, articles were assessed by 2 independent reviewers (CZ and RG) to summarize detailed information about each instrument according to the components of the OMERACT filter: feasibility, truth, and discrimination. Aspects of feasibility considered were cost, training required, equipment required, and patient acceptability. Aspects of truth considered were face validity (whether the method looks right), construct validity (whether the method relates to other methods of acute gout assessment in predicted ways, using correlation coefficients of patient level data), content validity (whether the methods cover the relative issues adequately, including any patient assessments), and internal consistency (whether Cronbach alpha was reported). Aspects of discrimination that were considered were within-group change sensitivity (in prospective studies, reported as effect size where available), and between-group sensitivity (differences documented between different allocated treatment groups in prospective studies with relevant statistics reported).

RESULTS

Summary of search results. The literature search identified 77 articles and abstracts that met the criteria for inclusion in the review. The search summary is outlined in Figure 1B. No studies explicitly addressed internal consistency using the specified definitions. Reproducibility data were not available for any instrument in the assessment of acute gout.

Pain. Pain was the most frequently reported domain (in 76 of the 77 studies assessed, Figure 1). Twenty different instruments were used in these studies to assess the pain of acute gout. The 3 most frequently used instruments are shown in Table 1. All 3 methods were considered feasible, with high face and content validity. The 100 mm (10 cm) pain visual analog scale (VAS) has been used in 16 studies of acute gout. Sensitivity to change for the pain VAS has been demonstrated with an effect size of 9.3 after 72 h following canakinumab 150 mg treatment. This instrument has also documented between-group discrimination in 2 separate clinical trials.

Similarly, the 5-point Likert pain scale has been used in 16 studies of acute gout, including a study of untreated acute gout. Sensitivity to change for the 5-point Likert scale has been demonstrated with effect sizes of 2.17–2.47 following 2 days of NSAID treatment. Between-group discrimination has been demonstrated in 2 separate clinical trials.

The 4-point Likert pain scale has been reported in 9 studies of acute gout. Sensitivity to change over time has been reported in many studies, although data were not available to allow calculation of effect sizes. Between-group discrimination has not been demonstrated.

Joint swelling. Joint swelling has been reported in 44 studies, using 15 different instruments (Figure 1). The 3 instruments most frequently used are shown in Table 2. All 3 instruments were considered feasible, although some observer training is required. Physician assessment of joint swelling in the index joint using a 4-point Likert scale (range 0–3) has been used in 8 studies of acute gout. This method has high face validity as it captures the degree of swelling in the affected joint, which is particularly relevant to acute gout, which frequently presents as a mono-arthritis. Sensitivity to change over time has been reported in many studies, although data were not available to allow calculation of effect sizes. Between-group discrimination has been reported in a clinical trial of canakinumab versus triamcinolone using this instrument. Several RCT comparing 2 NSAID have not shown differences in change in joint swelling using this instrument.

Physical measurement of the circumference of the affected joint using a tape measure has been reported in 7 acute gout studies. Although this method also allows assessment of the affected joint, there is a large variation in measurement depending on the size of the joint when large joints such as the knee and small joints such as those in the toes are included. Sensitivity to change over time has been demonstrated with an effect size of 0.46 following 3 days of NSAID treatment. Between-group discrimination has not been reported using this method.

Physician assessment of the swollen joint count (SJC) has been reported in 3 studies of acute gout. This instrument has the ability to measure the extent of disease in polyarticular gout, but does not capture the degree of swelling in an affected joint. This may reduce the sensitivity...
of the measure in patients with monoarticular gout, and SJC is not appropriate for studies of monoarticular gout. Within-group and between-group discrimination has been reported using this instrument (Table 2).

**Joint tenderness.** Joint tenderness has been reported in 39 studies, using 11 different instruments (Figure 1). The 3 instruments most frequently used are shown in Table 3. All 3 instruments were considered to be feasible, although some observer training is required. All instruments assessing joint tenderness may cause some patient distress, as joints

RCT: randomized controlled trial.
affected by acute gout may be extremely tender. Physician assessment of joint tenderness in the index joint using a 4-point Likert scale (range 0–3) has been used in 17 studies of acute gout. This method has high face validity because it captures the degree of tenderness in the affected joint. This is particularly relevant to acute gout, which frequently presents as a monoarthritis. Sensitivity to change over time has been reported in many studies, with effect size calculated as 2.5 following 3 days of high-dose piroxicam.

Between-group discrimination has been reported in a clinical trial of canakinumab versus triamcinolone using this instrument. Several RCT comparing 2 NSAID have not shown differences in change in joint tenderness using this instrument.

Physician assessment of joint tenderness in the index joint using a 5-point Likert scale (range 0–4) has been used in 5 studies of acute gout. As outlined above for the 4-point Likert scale, this method has high face validity because it captures the degree of tenderness in the affected joint. Sensitivity to change over time has been reported in a study of untreated acute gout, with effect size calculated as 0.9 on Day 7. A clinical study of intravenous indoprofen showed effect sizes of 2.1 after 2 h of treatment and 7.2 after 48 h.

Between-group discrimination has not been demonstrated.

Physician assessment of the tender joint count (TJC) has been reported in 3 studies of acute gout. As with the SJC, this instrument has the ability to measure the extent of disease in polyarticular gout, but does not measure the degree of tenderness in an affected joint. This may reduce the sensitivity of the measure in patients with monoarticular gout, and TJC is not appropriate for studies of monoarticular gout. Within-group and between-group discrimination has been reported using this instrument.

Patient global assessment. Patient global assessment has been reported in 25 studies of acute gout, using 19 different methods (Figure 1). Both patient global assessment of response to therapy (PGART) and patient global assessment of disease activity (PGA) have been reported. Of the 19 instruments, 10 were variations of the 5-point PGART instrument, using different descriptors, ranges, and methods of data collection. The 3 instruments used most frequently are shown in Table 4. All 3 methods were considered feasible, with high face and content validity. In contrast to the PGA, the PGART is a measure of change and does not allow measurement of patient assessment at baseline. A 5-point numerical PGART scale has been reported in 3 articles (see Table 4 for details of this scale). Sensitivity to change over time has been reported, although data were not available to allow calculation of effect sizes. Several RCT comparing 2 NSAID have not shown between-group differences in PGART response using this instrument.

A 5-point descriptive PGART scale has been reported in 2 clinical trials (see Table 4 for details of scale). Sensitivity to change over time has been reported, although data were not available to allow calculation of effect sizes. Two separate RCT comparing canakinumab with triamcinolone acetonide have shown between-group discrimination using this PGART instrument.

A 5-point PGA scale has been reported in 3 acute gout studies. Sensitivity to change over time has been reported in these studies, although data were not available to allow calculation of effect sizes. Two randomized controlled trials comparing 2 NSAID have not shown differences in change in PGA using this instrument.

Activity limitation. Activity limitation has been measured infrequently in studies of acute gout, with only 4 studies reporting this domain, using different instruments (Figure 1). Only 2 instruments, the Health Assessment Questionnaire (HAQ) and the Medical Outcome Study Short Form-36 Health Survey (SF-36) physical function (PF) domain have been reported in more than 1 study. Properties for these 2 instruments are shown in Table 5. Both instruments were considered to be feasible with high content and face validity. Both instruments have been endorsed by OMERACT for studies of chronic gout.

The HAQ has been reported in 2 acute gout studies. Sensitivity to change over time has been reported, with effect size in an observational study of acute gout calculated as 1.43 after > 1 month following treatment. An RCT comparing canakinumab with triamcinolone has not shown between-group discrimination.

The SF-36 has been reported in 2 studies of acute gout. However, data specifically related to the PF score has been reported in only 1 acute gout study, a clinical trial of canakinumab versus triamcinolone. Sensitivity to change over time was observed in this study, although data were not available to allow calculation of effect sizes. Differences between SF-36 PF scores were not reported between groups. However, this study did report that mean SF-36 PF scores in patients with acute gout were much lower than those for the general US population.

DISCUSSION
A key finding of this systematic literature review is that many different instruments have been used to assess the acute gout core domains. The wide variation observed in this review supports the need to standardize measurement of key domains in gout.

All the instruments identified within this review were considered feasible; these are low-cost tools that can be easily and rapidly administered without the need for specialist equipment. Any method that assesses joint tenderness may cause patient discomfort, particularly in the context of acute gout, which can cause exquisite joint tenderness. As in other articular diseases, careful training of observers is required to ensure that assessment of joint swelling and tenderness in patients with acute gout is undertaken in a manner that does not cause undue patient distress.

<td>Physician assessment of tenderness in the index joint using a 4-point Likert scale (range 0–3)</td>
<td>0 = no pain; 1 = mild pain; 2 = moderate pain; 3 = severe pain; 4 = very severe pain</td>
<td>Total: 17, observational: 5 (54–57, 60)</td>
<td>Inexpensive, some training required, no specialist equipment required, may cause patient distress</td>
<td>High face validity. The reduction in the number of patients with severe or moderate tenderness was accompanied by greater proportion of patients reporting no or mild pain on the 5-point Likert scale, the increasing proportion of patients reporting normalization of C-reactive protein, and better responses from PGART and IGART (18). Unable to calculate correlation coefficients with available information. Patients with both monoarticular and oligoarticular disease had a clinical response, but the response was greater in those with monoarticular disease, p &lt; 0.01 (42). Patients with both moderate and severe/extreme pain at baseline had a clinical response, but the response was greater in those with severe/extreme pain, p &lt; 0.05 (42). Measure captures degree of tenderness in affected joint.</td>
<td>All articles reported significant reduction in joint tenderness scores over time, typically by 72 h. In a clinical trial of 2 doses of piroxicam, mean tenderness score reduced from 2.10 at baseline to 0.54 on Day 3 and 0.15 on Day 7 in the high dose piroxicam group. ES = 2.5 on Day 3 and 2.9 on Day 7 (23).</td>
<td>In an RCT of canakinumab (CAN) vs triamcinolone acetontide (TA), the CAN 150 mg group had a lower tenderness score compared with the TA group 7 days post dose. The odds ratio favoring CAN 150 mg was 3.2 (95% CI, 1.27–7.9) (18). In 2 RCT comparing etoricoxib (ETO) and indomethacin (IND), there is no difference between the least square mean difference in tenderness scores between the ETO and IND groups (17, 20).</td>
</tr>
<tr>
<td>Physician assessment of tenderness in the index joint using Likert 0–4 (5-point scale)</td>
<td>0 = no tenderness, 1 = mild tenderness, 2 = moderate tenderness, 3 = severe tenderness and 4 = very severe tenderness</td>
<td>Total: 5; observational: 3 (16, 46, 47)</td>
<td>Inexpensive, some training required, no specialist equipment required, may cause patient distress</td>
<td>High face validity. Reduction in tenderness was accompanied by similar reduction in pain, swelling and restriction of joint movement (21, 46). Unable to calculate correlation coefficients with available information. Measure captures degree of tenderness in affected joint.</td>
<td>All articles reported significant reduction in joint tenderness scores over time, typically by 72 h following treatment. In untreated acute gout, tenderness scores were 3.9 at baseline, (Day 1), 3.9 on Day 2, and 3.1 on Day 7. ES = 0.0 on Day 2; and 0.9 on Day 7 (16). In clinical study of different dosing regimens of intravenous indoprofen, high dose bolus indoprofen lead to reduction of tenderness scores from 3.54 at baseline to 2.54 after 2 h, 1.46 after 4 h, 1.08 after 24 h, and 0.09 after 48 h. The ES from 2, 4, 24, and 48 h after the start of treatment were 2.1, 4.3, 5.1, and 7.2 respectively (21).</td>
<td>In a clinical trial of 2 dosage regimens of indopofen, there was no difference in the reduction in tenderness between 2 regimens (21). In a clinical trial comparing 2 antiinflammatory agents (IND and piroxicam), there was no difference in the reduction in tenderness between 2 agents (43).</td>
</tr>
<tr>
<td>Physician assessment of the number of tender joints (tender joint count, TJC)</td>
<td>0 = no pain; 1 = mild pain; 2 = moderate pain; 3 = severe pain; 4 = very severe pain</td>
<td>Total: 3; observational: 1 (26)</td>
<td>Inexpensive, some training required, no specialist equipment required, may cause patient distress</td>
<td>The reduction in the TJC was accompanied by reduction in tender joint count, pain VAS score, and C-reactive protein value, Leeds Foot Impact Scale and increase in the mean score of Lower Limb Task Questionnaire (26). Unable to calculate correlation coefficients with available information. Monoarticular flares are common in patients; in an RCT comparing etoricoxib (ETO) and indomethacin (IND), 99/150 patients had a single joint affected (17). Risk of floor effect. Degree of swelling not captured within the measure.</td>
<td>All treatments led to significant reduction in SJC over time, with the exception of the herbal formula Danggu-Nian-Tong-Tang (DNTT) (28). Following IND treatment, mean (SD) SJC reduced from 1.3 (0.7) at baseline to 0.6 (0.5) after 72 h ES = 0.22 (28). In an observational study, mean (SD) SJC reduced from 3 (3) at baseline to 0 (1) at the followup visit (≥1 month after treatment). ES = 0.67 (26).</td>
<td>In an RCT comparing DNTT with IND, there was a significant difference between the groups in TJC after 72 h of treatment; mean (SD) TJC for DNTT 2.6 (2.4), and IND 0.6 (0.7), p = 0.001 (28). In an RCT of 2 dosage regimens of piroxicam, there was no significant difference in TJC between high-dose and low-dose piroxicam (23).</td>

RCT: randomized controlled trial.
Most of the instruments commonly used to measure acute gout core domains have high face validity. Gout frequently presents as a monoarthritis, thereby allowing for rapid improvement in the clinical features of inflammation and tenderness. This was clearly demonstrated in a study of untreated acute gout, which showed significant reductions in tender joint count, swollen joint count, and patient global assessment of response to treatment (PGART) within 1 week after treatment. ES = 1.43 (26).

In an RCT of canakinumab (CAN) vs triamcinolone acetonide (TA), reductions in HAQ-DI scores ranged from 0.46–0.67 at Day 7, and 0.52–0.85 at Week 8 across the groups (26). SF-36 questionnaire has been endorsed by OMERACT and has been used in > 1 study. No articles reported internal validity, feasibility, or test-retest reproducibility. Effect size (ES) is provided wherever possible. If the ES could not be calculated, the statistic and associated p value are provided. References are represented as numerals in parentheses.
Further, because of the severe nature of pain caused by acute gout, it is now considered unethical to undertake placebo-controlled trials of acute gout. The majority of clinical trials identified in the literature search were equivalence and safety NSAID studies, typically with indomethacin as the active comparator. Thus, assessment of between-group discrimination for the purposes of the OMERACT filter is somewhat limited. However, several studies did allow analysis of between-group discrimination, particularly a placebo-controlled study of colchicine published in 1987\(^7\), an RCT comparing high-dose and low-dose celecoxib\(^9\), several RCT comparing canakinumab with triamcinolone\(^13,18\), and a study comparing a Chinese herbal medication with indomethacin\(^28\). Although the minimal important difference has not been reported for instruments assessing acute gout, statistical differences could be detected both within and between groups for the following measures: pain VAS, 5-point pain Likert score, 4-point physician assessments of index joint swelling and tenderness, TJC, SJC, and PGART.

With regards to the OMERACT filter cube taxonomy of discrimination\(^29\), all studies report statistical differences because the minimal relevant difference or important differences have not been determined for acute gout, so all change indices are located in the first column of the cube. All studies look at group settings so all change indices are located in the front face of the cube. For the studies that report a within-group change, those data are clearly in the second floor of the cube but for between-group differences, some comparisons concerned change scores (top floor of the cube) and others concerned final scores (bottom floor of the cube).

Many different instruments have been used to assess the acute gout core domains. Pain VAS and 5-point Likert scales, 4-point Likert scales of index joint swelling and tenderness, and 5-point PGART instruments meet the criteria for the OMERACT filter. Further research is required to validate measures of activity limitation for studies of acute gout.
