Pulmonary involvement because of amyloidosis is rare in Sjögren syndrome (SS). It can be treated with corticosteroids.

A 40-year-old woman presenting with dry cough, dyspnea score Moser 1, chest pain, and fatigue was investigated for suspected interstitial pulmonary disease. Fifteen years earlier, she had been diagnosed with SS on the basis of sicca syndrome, positive salivary glands biopsy, antinuclear antibody > 1:640 (granular pattern), and high titer anti-La and anti-Ro antibodies. Physiological lung function showed an initial restrictive pattern with normal carbon monoxide transfer. High-resolution computed tomography (HRCT) identified multiple pulmonary nodules (Figure 1A), which showed intense uptake on a positron emission tomography/CT scan (Figure 1B). QuantiFERON (Quest Diagnostics) test was negative. To exclude possible lung cancer, a biopsy of one of the nodules was performed. Histopathological evaluation showed peribronchial and perivascular lymphoid nodular hyperplasia, with perivascular and interstitial amyloid deposits seen after use of dye (Figure 1C, arrows). The patient was prescribed prednisone at an initial dose of 25 mg daily for 1 month, which was tapered over 6 months to 5 mg daily with a complete resolution of the symptoms.

Pulmonary involvement because of amyloidosis is rare in SS, occurring in only 2/343 of the patients (0.6%) studied by Strimlan, et al. A biopsy of nodular amyloidosis of the lung has revealed amyloid light-chain type or transthyretin amyloidosis.
