Letter

Dr. Trefond et al reply

To the Editor:

We thank Conway et al1 for their comments on our article reporting a case of giant cell arteritis (GCA) after SARS-CoV-2 vaccination.2 We agree with Conway et al1 and also emphasize the interest in SARS-CoV-2 vaccination, which had a reassuring safety profile in a cohort of 1519 patients with rheumatic and musculoskeletal diseases.3

Indeed, the association between GCA and the SARS-CoV-2 vaccination could have been pure coincidence, but we know that there are trigger factors without being able to confirm if they are causal factors. This association has also been reported in anti-neutrophil cytoplasmic antibody–associated vasculitis4 and we agree that we need large epidemiological studies to ascertain the potential relationship.

In the title of our study, we emphasized the particular phenotype of this case, which was a low level of C-reactive protein (CRP).2 The random incidence of GCA in France estimated by Conway et al1 would be very different with low levels of CRP. In our cohort from 2004 to 2020 of 116 patients with positive temporal artery biopsy (TAB), we had 2 patients (1.7%) with an initial CRP level < 10 mg/L and none ≤ 5 mg/L (unpublished data). The proportion was similar (2/119, 1.7%) in the cohort from Parikh et al5 in 2006.

Our message2 was addressed not to the general population but to clinicians so as to help in diagnosis. Patients may indeed pay more attention to their symptoms after vaccination since they are asked to do so, but some diagnoses can hide behind these symptoms, and we know the potential damage caused by GCA. Patient history should include vaccinations. Further, when the symptoms presented are compatible with GCA, a CRP level ≤ 5 mg/L should not rule out a GCA diagnosis and a TAB should be performed.
